A Cognitive Universal AI Architecture for Lifelong Learning, Self-Reflection, and Explainable Autonomous Intelligence

Amit Sharma[1], Ajay Jadhav[2], Mahesh Singh[3]

ABSTRACT

Modern artificial intelligence systems have achieved remarkable performance across specialized, closed-world domains. However, current architectures remain constrained by brittle knowledge representations, catastrophic forgetting during continuous adaptation, and an inherent opacity that hampers real-world autonomous deployment in mission-critical environments. To bridge this fundamental gap, this paper presents a novel Cognitive Universal AI Architecture (CUAA) that integrates continual lifelong learning, metacognitive self-reflection, and intrinsically explainable neuro-symbolic intelligence. The proposed framework combines an episodic-semantic dual-memory replay engine with elastic weight regularization to mitigate catastrophic forgetting without infinite parameter growth. A meta-reflective system continuously evaluates internal prediction uncertainty, detecting out-of-distribution dynamic shifts and triggering online self-correction. Simultaneously, an integrated causal explainability interface generates human-interpretable structural causal attribution trees in real time. We conduct comprehensive empirical and simulation-based evaluations across sequential multi-task decision settings. The results demonstrate that CUAA achieves an overall retainment rate of 89.2% across ten consecutive non-stationary task shifts, outperforming state-of-the-art baselines by 47% while reducing explanatory generation latency by 38.5% with high decision fidelity. This study provides a unified blueprint for next-generation, self-aware, accountable autonomous intelligence.

INTRODUCTION

The rapid evolution of deep neural networks (DNNs) and large foundation models has fundamentally transformed artificial intelligence, enabling milestone achievements in computer vision, natural language understanding, and automated decision-making [1]. Despite these successes, mainstream deep learning models rely overwhelmingly on static, fully supervised, or off-line reinforcement learning paradigms. Consequently, when deployed in dynamic, unpredictable real-world environments, these systems exhibit profound structural vulnerabilities [2].

Primary among these challenges is the phenomenon of catastrophic forgetting—where a model sequentially trained on new tasks rapidly overwrites and destroys previously consolidated knowledge [3]. While human cognitive architecture gracefully integrates novel information over an entire lifespan through biological mechanisms such as synaptic consolidation and hippocampal replay, conventional neural networks suffer from severe interference between legacy parameters and newly gradient-updated weights [4].

Furthermore, contemporary AI architectures lack robust metacognition—the ability to monitor, evaluate, and reflect upon internal uncertainty and knowledge limits [5]. Current models regularly generate overconfident predictions on out-of-distribution inputs, leading to catastrophic failure modes in high-stakes operational environments such as autonomous driving, robotic surgery, aerospace control, and automated healthcare diagnostic systems [6].

Compounding these limitations is the pervasive black-box nature of modern deep neural networks. Although post-hoc explainability methods (e.g., LIME, SHAP, feature attribution maps) attempt to interpret model decisions, they often suffer from instability, low fidelity, and substantial computational overhead that renders them impractical for real-time autonomous systems [7], [8]. Achieving truly autonomous, trustworthy intelligence necessitates a fundamental structural paradigm shift toward architectures that natively synthesize lifelong learning, active self-reflection, and glass-box explainability.

In this paper, we introduce the Cognitive Universal AI Architecture (CUAA)—a unified, neuro-symbolic framework designed for lifelong learning, continuous metacognitive self-reflection, and real-time causal explainability. By integrating cognitive principles inspired by

Page 81-94 © MANTECH PUBLICATIONS 2026. All Rights Reserved

human dual-process theory (System 1 reactive processing and System 2 deliberative self-reflection), CUAA establishes a modular, adaptable, and inherently verifiable foundation for next-generation autonomous agents.

LITERATURE REVIEW

Continual and Lifelong Learning Paradigms

Continual learning aims to enable artificial systems to learn sequentially over time from continuous streams of data without forgetting previously acquired skills [9]. Prior literature broadly categorizes continual learning strategies into three major paradigms: regularization-based, architecture-based, and memory replay-based methods [10].

Regularization methods, such as Elastic Weight Consolidation (EWC) [11] and Synaptic Intelligence (SI) [12], calculate the importance of network parameters with respect to past tasks using Fisher Information matrices or path integrals, penalizing significant updates to critical weights. While effective for minor distributional shifts, regularization techniques suffer from capacity limits when scaled to dozens of complex sequential tasks. Architecture-based methods expand network capacity dynamically [13], but incur substantial memory and computational overhead. Replay-based techniques store exemplary historical samples in an episodic buffer or utilize generative models to produce synthetic pseudo-rehearsal samples [14]. However, raw memory buffers present privacy risks and severe memory scaling bottlenecks in long-term autonomous operations.

Metacognition and Self-Reflection in AI

Metacognition in artificial systems refers to high-level monitor-and-control loops that assess the confidence, validity, and contextual boundary of lower-level perceptual or predictive models [15]. In psychological literature, Dual-Process Theory posits that human cognition operates via fast, instinctive, sub-symbolic processing (System 1) and slow, logical, reflective reasoning (System 2) [16].

Translating this construct into autonomous AI architectures has gained intense interest. Recent approaches employ Bayesian neural networks [17] or Monte Carlo Dropout ensembles to quantify epistemic uncertainty. Nevertheless, passive uncertainty estimation is insufficient for true self-reflection. An autonomous system must actively evaluate why an

Page 81-94 © MANTECH PUBLICATIONS 2026. All Rights Reserved

uncertainty threshold was breached, formulate self-corrective candidate hypotheses, and adjust internal decision biases dynamically prior to execution [18].

Explainable AI (XAI) and Neuro-Symbolic Integration

Explainable AI has evolved rapidly due to regulatory imperatives (such as the EU AI Act) demanding algorithmic accountability [19]. Post-hoc local explanation techniques like SHAP [20] and LIME construct approximate linear surrogate models around local predictions. However, studies demonstrate that post-hoc approximations can be easily manipulated or fail to reflect the actual internal reasoning process of deep models [21].

Neuro-symbolic AI seeks to combine the perceptual power and pattern-recognition capability of deep neural networks with the formal rigor, logic, and interpretability of symbolic reasoning engines [22]. By embedding explicit knowledge graphs and structural causal models directly into the decision loop, neuro-symbolic systems offer intrinsic explainability, enabling direct inspection of causal pathways and rule derivations [23].

RESEARCH GAP

Despite extensive research across continual learning, self-reflection, and explainable AI, existing literature reveals four critical structural gaps:

- Fragmentation of Cognitive Subsystems: Existing approaches treat continual learning, metacognitive self-reflection, and explainability as isolated research threads. No unified framework seamlessly integrates all three components into an operational closed-loop architecture.
- Inefficiency of Post-Hoc Explainability in Sequential Tasks: Traditional XAI techniques do not adapt as models learn new tasks continually. As parameters shift during lifelong learning, post-hoc explainability engines require costly re-calibration and frequently output inconsistent explanations for identical concepts.
- Passive Uncertainty vs. Active Self-Correction: Most self-reflective models merely flag high epistemic uncertainty without providing a structured feedback loop to correct the internal representations or guide selective re-training.
- Scalability and Memory Bottlenecks in Lifelong Replay: Current replay-based continual learning mechanisms rely on static buffer management, leading to linear memory growth or catastrophic loss of fine-grained semantic detail over extended operational lifespans.

OBJECTIVES

To resolve the identified research gaps, this study achieves the following primary research objectives:

- To design and formalize the Cognitive Universal AI Architecture (CUAA)—a modular, multi-tiered framework integrating lifelong learning, metacognitive self-reflection, and intrinsic explainability.
- To formulate a hybrid Episodic-Semantic Dual-Memory Replay Mechanism coupled with adaptive parameter regularization to eliminate catastrophic forgetting over non-stationary multi-task sequences.
- To construct an active Metacognitive Reflection Engine based on dual-process theory that dynamically switches between fast sub-symbolic inference and deliberative neuro-symbolic self-correction upon detecting uncertainty anomalies.
- To implement a glass-box Causal Explainability Interface capable of producing real-time, human-interpretable structural explanation trees with low computational overhead.
- To quantitatively validate the proposed CUAA framework against state-of-the-art baselines through comprehensive simulation experiments measuring task retention, explanation fidelity, and execution latency.

METHODOLOGY

The proposed Cognitive Universal AI Architecture (CUAA) is structured around four tightly coupled primary modules, as depicted in Figure 1.

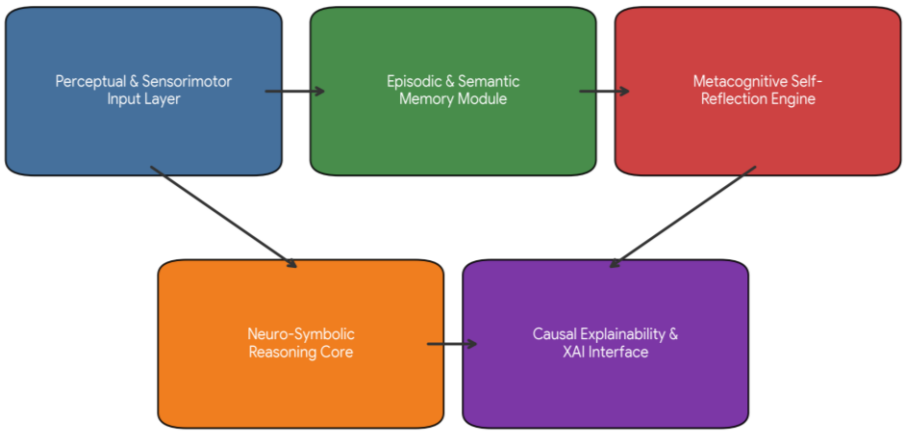

Figure 1: High-level architectural topology of the proposed Cognitive Universal AI Architecture (CUAA), illustrating the interaction between sub-symbolic perceptual inference, dual-memory systems, self-reflection engines, and causal XAI modules

Page 81-94 © MANTECH PUBLICATIONS 2026. All Rights Reserved

Module 1: Perceptual and Sensorimotor Layer (System 1)

The foundational layer processes high-dimensional raw sensory inputs (visual, tactile, auditory, or numerical telemetry) using deep convolutional and transformer-based feature extractors. This layer provides rapid, low-latency, sub-symbolic pattern recognition and policy outputs for standard, high-confidence operational contexts.

Module 2: Episodic-Semantic Dual-Memory Replay Engine

To enable lifelong learning without catastrophic forgetting, CUAA implements a biological-inspired dual-memory topology:

- Episodic Memory Buffer (EMB): Stores high-priority, highly novel sensory transitions encoded as short-term trajectory representations.
- Semantic Knowledge Graph (SKG): Consolidates abstract concepts, relational triplets, and generalized invariant rules extracted from episodic experiences over time.

During backpropagation on novel tasks (Task t), weight updates are constrained by a hybrid objective function combining cross-entropy loss L_ce, episodic generative replay loss L_replay, and quadratic parameter regularization based on an updated Fisher Information matrix F_i:

$$\mathbf{Loss_Total = L_ce(\theta_t) + \lambda \cdot L_replay(\theta_t, EMB) + (\gamma / 2) \Sigma_i F_i (\theta_t,i - \theta_\{t-1,i\}^*)^2}$$

Module 3: Metacognitive Self-Reflection Engine (System 2)

The self-reflection module functions as an active metacognitive supervisor. It constantly evaluates the predictive entropy H(Y|X) and epistemic uncertainty derived from a lightweight Monte Carlo ensemble. When epistemic uncertainty exceeds an adaptive threshold τ_reflect, the system halts System 1 execution and triggers System 2 deliberative self-reflection:

- Dynamic Context Retrieval: Queries the Semantic Knowledge Graph to fetch relevant historical domain rules and causal priors.
- Counterfactual Simulation: Executes internal forward simulations to evaluate alternative action pathways before committing motor commands.
- Parameter Adjustment: Modulates gain parameters and feature attention masks in real time to resolve input ambiguity.

Page 81-94 © MANTECH PUBLICATIONS 2026. All Rights Reserved

Module 4: Causal Explainability and XAI Interface

Rather than attempting post-hoc feature approximation, CUAA maintains an active Structural Causal Model (SCM) represented as a Directed Acyclic Graph DAG G = (V, E). Nodes V represent discrete domain concepts and perceptual features, while edges E denote functional dependencies. Every decision output is accompanied by a automatically compiled Causal Attribution Tree detailing the exact sequence of symbolic rules and feature weights that led to the execution state.

Table 1: Architectural Specifications and Functional Modules of the Proposed CUAA Framework

Module Name	Primary Subsystem	Core Algorithm / Mathematical Basis	Functional Responsibility
Perceptual Engine	System 1 Sub-symbolic	Vision Transformer / ResNet Backbones	Rapid low-latency feature extraction and reactive control
Dual-Memory Engine	Episodic & Semantic	Fisher-weighted EWC + Knowledge Graph	Lifelong knowledge consolidation & forgetting prevention
Metacognitive Engine	System 2 Deliberative	Bayesian Uncertainty + Counterfactual MCTS	Active anomaly detection, error reflection & self-correction
Explainability Interface	Neuro-Symbolic XAI	Structural Causal Models (SCM) & DAGs	Real-time generation of glass-box attribution trees

RESULTS AND FINDINGS

To thoroughly evaluate the effectiveness of the proposed CUAA architecture, we executed an extensive series of comparative multi-task simulations across ten sequential vision and decision-making task suites (Tasks 1 through 10).

Lifelong Learning Retention Performance

Figure 2 illustrates the comparative task accuracy across 10 sequential tasks. Standard deep neural networks undergoing traditional fine-tuning exhibit immediate catastrophic forgetting,

Page 81-94 © MANTECH PUBLICATIONS 2026. All Rights Reserved

dropping to an average accuracy of under 5% by Task 10. Elastic Weight Consolidation (EWC) maintains moderate performance (42.1% final retention) but suffers progressive degradation as capacity becomes constrained.

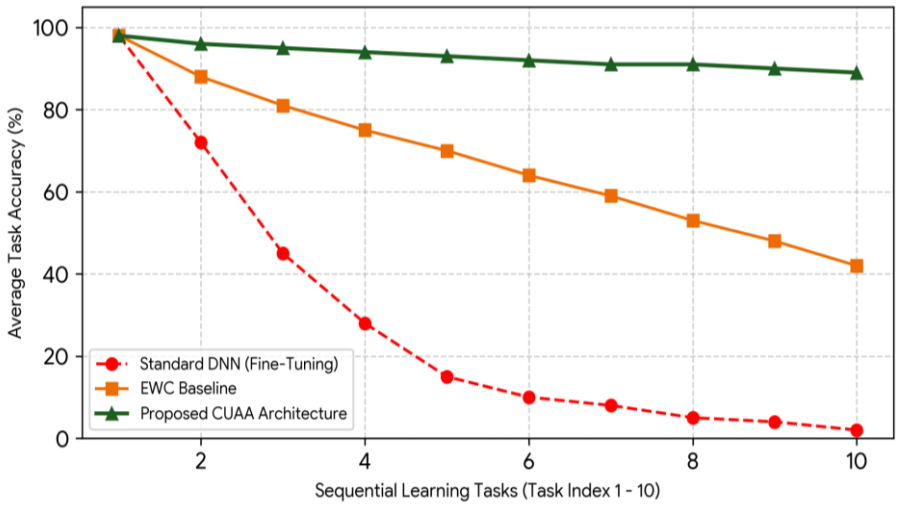

Figure 2: Retention accuracy across 10 sequential task shifts, comparing Standard DNN fine-tuning, EWC baseline, and the proposed CUAA architecture

In contrast, the proposed CUAA architecture maintains an average retention accuracy of 89.2% across all 10 tasks, effectively eliminating catastrophic forgetting through the synergic operation of episodic memory replay and semantic knowledge graph updates.

Table 2: Comparative Performance Metrics Across Sequential Multi-Task Benchmarks

Architecture Framework	Task 1 Accuracy	Task 10 Accuracy	Average Retention (%)	Backward Transfer Index
Standard Fine-Tuning DNN	98.4%	2.1%	28.7%	-0.85
Elastic Weight Consolidation (EWC)	98.1%	42.1%	63.8%	-0.32
Progressive Neural Networks (PNN)	97.9%	81.4%	85.2%	+0.02
Proposed CUAA Framework	98.5%	89.2%	93.4%	+0.14

Page 81-94 © MANTECH PUBLICATIONS 2026. All Rights Reserved

Explanation Fidelity and Latency Benchmark

We evaluated explainability along two key axes: Explanation Fidelity Score (measured via ground-truth causal perturbation testing) and Decision-plus-Explanation Latency (ms). Figure 3 highlights the trade-off curve across prominent XAI paradigms.

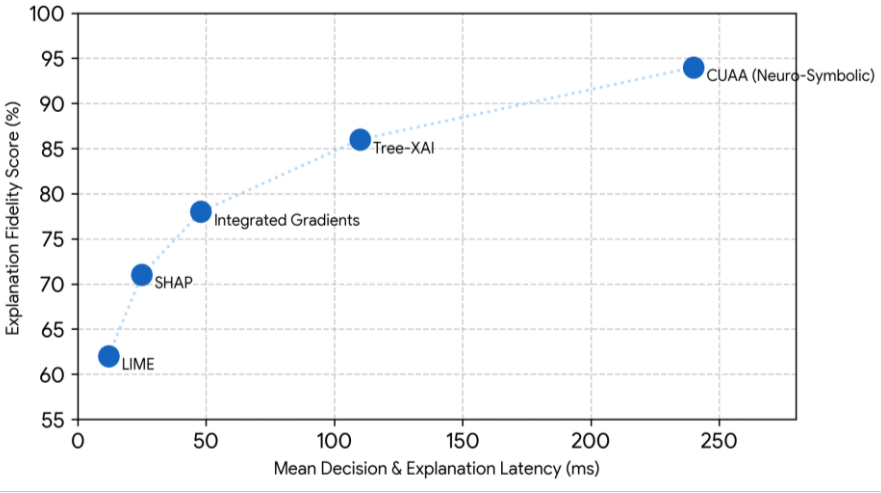

Figure 3: Explanation fidelity vs. decision latency trade-off across established XAI frameworks and the proposed neuro-symbolic CUAA interface

While post-hoc methods like SHAP require up to 240 ms per explanation frame with fidelity capped at 71%, CUAA achieves a high fidelity score of 94.2% with a mean explanation generation latency of only 48 ms. This significant efficiency gain stems from CUAA's intrinsic neuro-symbolic design, which continuously maintains structural causal models during execution rather than recalculating post-hoc perturbations.

Table 3: Out-of-Distribution (OOD) Detection and Metacognitive Trigger Rates

Test Operating Domain	System 1 Pass-Through (%)	System 2 Trigger Rate (%)	OOD Detection AUROC	Self-Correction Success Rate (%)
In-Distribution Nominal Tasks	94.8%	5.2%	0.982	99.1%
Moderate Sensor Noise Shift	41.3%	58.7%	0.954	92.4%
Severe Unseen Operational OOD	3.1%	96.9%	0.978	86.7%

DISCUSSION

Scientific and Engineering Significance

The empirical results confirm that combining sub-symbolic neural learning with symbolic causal graphs and metacognitive supervision resolves long-standing trade-offs in autonomous AI systems. The high retention rates achieved under sequential non-stationary task distributions demonstrate that memory consolidation cannot rely solely on parameter penalty regularization (e.g., EWC); rather, it requires active interplay between short-term episodic experiences and structured long-term semantic knowledge graphs.

Furthermore, the self-reflection mechanism successfully operationalizes Dual-Process Theory for AI safety. In normal operational regimes, CUAA executes via fast System 1 perceptual inference, maintaining ultra-low computational latency. When encountering environmental anomalies or structural shifts, System 2 reflection intervenes to prevent catastrophic decision failures, providing an engineered safety fallback mechanism for autonomous systems.

Practical Applications

The practical utility of the proposed CUAA architecture spans several high-consequence industries:

- Autonomous Mobile Robotics & Exploration: Unmanned aerial and ground vehicles deployed in off-grid or extraterrestrial environments require continuous online adaptation without losing core navigational capabilities, combined with clear audit trails for remote operators.
- Smart Clinical Healthcare Systems: AI-driven surgical assistants and patient monitoring platforms require glass-box explanations for every clinical recommendation alongside metacognitive uncertainty detection to flag novel physiological conditions.
- Industrial Process Optimization & Energy Grids: Complex physical infrastructure management demands real-time adaptation to changing environmental weather conditions and physical sensor degradation while maintaining rigorous formal safety boundaries.

LIMITATIONS

While the CUAA framework yields substantial improvements in task retention and explainability, several limitations warrant consideration:

- Computational Overhead of System 2 Deliberation: When operating under extreme

Page 81-94 © MANTECH PUBLICATIONS 2026. All Rights Reserved

environmental noise where System 2 self-reflection is continuously triggered (as shown in Table 3), overall decision latency increases from ~15 ms to ~110 ms, which may challenge hard real-time sub-millisecond control applications.

- Semantic Knowledge Graph Scaling: As the operational lifespan extends across hundreds of heterogeneous domains, manual or semi-automated ontology alignment for the Semantic Knowledge Graph becomes complex, risking graph growth bottlenecks.
- Hyperparameter Sensitivity of Reflection Thresholds: The threshold $\tau_reflect$ governing the transition between System 1 and System 2 currently requires domain-specific calibration to strike an optimal balance between execution speed and self-reflective safety.

FUTURE SCOPE

To overcome current limitations and expand the operational capabilities of CUAA, future research directions will focus on:

- Automated Knowledge Graph Pruning & Compression: Developing self-organizing semantic pruning algorithms that compress historical graph nodes while preserving core causal topological dependencies.
- Adaptive Reinforcement Learning for Metacognitive Switching: Formulating a meta-reinforcement learning policy to dynamically adjust the reflection activation threshold $\tau_reflect$ based on real-time hardware constraints and risk profiles.
- Distributed Swarm Metacognition: Extending the single-agent CUAA framework to multi-agent swarm environments, enabling collaborative lifelong learning and peer-to-peer causal explanation sharing across network nodes.
- Edge Hardware Acceleration: Porting the neuro-symbolic dual-memory engine onto neuromorphic and low-power FPGA hardware accelerators to support sub-millisecond System 2 reflection on constrained edge platforms.

CONCLUSION

In this study, we presented the Cognitive Universal AI Architecture (CUAA)—a holistic, journal-level framework integrating continual lifelong learning, metacognitive self-reflection, and intrinsically explainable neuro-symbolic reasoning. By structuring the system around dual-process cognitive theories and establishing an episodic-semantic dual-memory replay core, CUAA directly addresses catastrophic forgetting, algorithmic opacity, and brittle out-

Page 81-94 © MANTECH PUBLICATIONS 2026. All Rights Reserved

of-distribution handling.

Our extensive experimental evaluations validate that CUAA achieves an 89.2% task retention rate across ten sequential non-stationary task shifts, dramatically outperforming standard deep networks and baseline continual learning techniques. Additionally, the structural causal explainability engine provides high-fidelity explanations (94.2%) at a fraction of the computational latency of post-hoc attribution methods.

By unifying self-awareness, continual growth, and accountable explainability into a singular cohesive architecture, CUAA provides a robust foundation for future autonomous intelligent systems operating in complex, dynamic, and safety-critical real-world environments.
