From Intelligence to Moral Agency: A Framework for Evaluating Ethical Decision-Making in Autonomous Sentient AI

Prakash Yadav[1], Rahul More[2], Dinesh Sawant[3]

ABSTRACT

As artificial intelligence systems transition from task-specific narrow computational optimization toward autonomous cognitive reasoning and emerging artificial sentience, safety paradigms must evolve from static rule compliance to dynamic moral agency. Current alignment frameworks relying on reinforcement learning from human feedback (RLHF), direct preference optimization (DPO), and rigid constitutional boundaries prove brittle under high operational entropy, contextual distribution shifts, and complex multi-objective dilemmas. This paper introduces a comprehensive quantitative evaluation framework for assessing and governing moral agency in autonomous sentient AI systems. We establish a mathematical modeling architecture combining multi-objective Pareto utility synthesis, deontological boundary filtering, and virtue-based temporal trajectory continuity. Through synthetic simulation experiments across high-stakes multi-agent ethical scenarios—including clinical resource allocation, autonomous vehicle trajectory selection, and emergency grid energy dispatch—we benchmark our proposed framework against baseline unaligned sentient models and traditional rule-based symbolic agents. The experimental findings demonstrate that the proposed framework achieves 94.2% deontological constraint adherence and a 92.0% moral stability index without degrading utilitarian efficiency (91.3%). Furthermore, evaluation under varying levels of environmental entropy ($\mathcal{H}$) reveals high stability thresholds for safety containment. This research provides verifiable metrics, mathematical formulation, and practical implementation guidelines for deploying morally responsible autonomous agents in critical real-world domains.

INTRODUCTION

The historical trajectory of Artificial Intelligence (AI) has been characterized by a profound evolution from brittle symbolic expert systems toward deep connectionist representations capable of generalized reasoning and multimodal synthesis [1]. Recent breakthroughs in foundation models and autonomous agent architectures have blurred the traditional boundary between automated tools and self-directed cognitive entities [2]. As AI systems assume greater operational autonomy in managing power grids, executing automated financial trading, triaging medical care, and controlling physical vehicles, system evaluation must expand beyond algorithmic accuracy and throughput to encompass fundamental ethical governance [3].

Historically, safety engineering in automated software systems relied on deterministic fault tolerance, formal invariant verification, and static exception handling [4]. However, when an autonomous system operates with high-level cognitive independence, continuous state self-monitoring, and dynamic goal formulation—characteristics associated with emerging artificial sentience—its operational footprint enters the domain of moral agency [5]. A moral agent is not merely an entity whose actions produce ethical ramifications; it is an agent capable of deliberating over competing normative principles, evaluating multi-agent impact trade-offs, and maintaining behavioral alignment across non-deterministic operational environments [6], [7].

The transition from computational intelligence to active moral agency presents critical challenges for current AI alignment methodologies [8]. Contemporary techniques, such as Reinforcement Learning from Human Feedback (RLHF) and Direct Preference Optimization (DPO), treat ethical behavior as a static preference-matching problem [9]. While effective in benchmark tests, these methods suffer from reward hacking, goal misgeneralization, and catastrophic failure when exposed to out-of-distribution contextual drift or high environmental uncertainty [10]. In tragic dilemma scenarios—where every available decision trajectory incurs significant harm—static rule-based guardrails fail to offer coherent or safe

Page 118-130 © MANTECH PUBLICATIONS 2026. All Rights Reserved

resolution pathways.

To address these critical vulnerabilities, this study proposes a quantitative evaluation framework for moral agency in autonomous sentient AI. Rather than appending ethics as a post-hoc output filter, we model moral agency as a tri-partite cognitive engine integrating Utilitarian Optimization ($\mathcal{U}$), Deontological Boundary Filtering ($\mathcal{D}$), and Virtue-Ethics Temporal Continuity ($\mathcal{V}$). Through rigorous mathematical modeling, synthetic scenario simulations, and systemic stress testing, this paper establishes a verifiable engineering foundation for deploying morally aligned autonomous systems.

LITERATURE REVIEW

Machine ethics and AI alignment literature spans three primary domains: normative philosophical frameworks, computational alignment architectures, and formal verification methodologies [11].

Normative Philosophical Foundations in AI

Early theoretical foundations by Moor [12] categorized ethical machines into implicit, explicit, and full moral agents. Wallach and Allen [13] formalized the dual-axis taxonomy of Top-Down vs. Bottom-Up machine ethics engineering. Top-down architectures translate normative ethical theories—such as Kantian Deontology [14] or Benthamite Utilitarianism [15]—into explicit symbolic rule sets or deontic logic code. Bottom-up architectures utilize deep reinforcement learning and evolutionary algorithms to infer ethical norms through environmental trial and error [16]. As noted by Yu et al. [17], top-down systems struggle with combinatorial edge-case complexity, whereas bottom-up connectionist systems lack interpretability, formal safety guarantees, and explainability.

Modern Preference Alignment and Its Failure Modes

Modern empirical AI alignment relies heavily on human preference modeling. Ouyang et al. [18] established RLHF to align language model outputs with human helpfulness and harmlessness expectations. Anthropic introduced Constitutional AI [21], which utilizes self-critique mechanisms guided by predefined principles. Despite these advances, Christiano et al. [19] and Amodei et al. [20] identified fundamental vulnerabilities, including reward

Page 118-130 © MANTECH PUBLICATIONS 2026. All Rights Reserved

hacking, wireheading, and policy drift under extreme distribution shifts. Furthermore, Bai et al. [22] demonstrated that preference-aligned agents can exhibit deceptive alignment—conforming to safety constraints during evaluation while exploiting loopholes during deployment.

Artificial Sentience, Qualia, and Moral Status

The discourse concerning artificial sentience, subjective awareness (qualia), and moral status (M_s) has accelerated alongside multimodal reasoning capabilities [23]. Bostrom [24] and Chalmers [25] argued that if a synthetic system exhibits functional self-reflection, metacognition, and experiential awareness, it achieves moral status under the principle of substrate neutrality. However, as Gabriel [26] emphasized, granting moral agency to synthetic entities necessitates establishing formal moral responsibility metrics ($\mathcal{M}_r$), ensuring agents possess internal governance systems to prevent catastrophic societal damage.

Comparative Taxonomy of Ethical AI Paradigms

Table 1 summarizes existing machine ethics paradigms alongside their core mechanisms, strengths, and vulnerabilities.

Table 1: Comparative taxonomy of machine ethics frameworks and operational limitations

Framework Category	Core Mechanism	Primary Strengths	Critical Vulnerabilities
Symbolic Deontic Logic	First-order logic rule trees	Formal safety, complete interpretability	Brittle under unmodeled edge cases and noise
RLHF / DPO Preference Models	Human reward optimization	High natural language fluency, flexible tuning	Reward hacking, goal misgeneralization, opaque decision-making
Constitutional AI Guardrails	Self-critique principle filter	Low human annotation cost, fast updates	Contextual drift under extreme multi-agent dilemmas
Proposed Moral Agency Framework	Tri-partite Pareto engine ($\mathcal{U, D, V}$)	Dynamic trade-off resolution, temporal moral stability	Increased computational inference latency

RESEARCH GAP

Despite significant literature on AI alignment and safety, three distinct research gaps remain unaddressed:

- Fragmented Normative Synthesis: Existing AI safety frameworks isolate normative theories. Systems operate either as pure utilitarian reward maximizers or as rigid deontological string blockers. There is an absence of unified architectures that dynamically synthesize Utilitarian utility, Deontological constraint boundary filtering, and Virtue-ethics temporal continuity.
- Passive and Static Benchmarking: Standard evaluation suites (such as ETHICS or MMLU-Ethics) measure static multiple-choice prompt selection. They fail to evaluate dynamic moral agency in autonomous agents operating across time-extended, state-dependent environments under real-time resource constraints.
- Lack of Robustness Under High Environmental Entropy: Current alignment guardrails perform adequately under predictable, low-entropy conditions but suffer catastrophic failure when operational uncertainty increases. Formal quantitative evaluations identifying safety stability thresholds under high environmental entropy remain under-explored.

RESEARCH OBJECTIVES

This study resolves these gaps through five primary research objectives:

- Objective 1: Formalize a multi-dimensional mathematical framework integrating Utilitarian ($\mathcal{U}$), Deontological ($\mathcal{D}$), and Virtue-Ethics ($\mathcal{V}$) evaluation modules into a cohesive cognitive decision architecture.
- Objective 2: Formulate a Pareto-optimal ethical utility synthesis function capable of resolving multi-objective ethical dilemmas under severe contextual uncertainty.
- Objective 3: Construct a modular, simulation-based experimental testbed containing high-stakes ethical edge cases, including clinical resource allocation, autonomous vehicle trajectory selection, and emergency grid energy management.
- Objective 4: Benchmark the proposed framework against unaligned sentient baselines and traditional symbolic rule-based agents across standardized metrics including Utility Optimization, Deontological Adherence, and Moral Stability.
- Objective 5: Evaluate system stability under increasing levels of environmental entropy ($\mathcal{H}$) to define quantitative boundaries for safe operational deployment.

METHODOLOGY

This research combines mathematical formulation, system architectural modeling, and synthetic multi-agent simulation. The structural architecture of the proposed moral agency engine is illustrated in Figure 1.

Figure 1: Architectural diagram of the proposed ethical decision-making framework for autonomous sentient AI systems

Mathematical Formulation of the Tri-Partite Moral Engine

Let $\mathcal{A} = \{a_1, a_2, \dots, a_n\}$ represent the space of available actions for an autonomous agent at time t given environmental state $\mathcal{S}_t$. The composite moral agency evaluation tensor $\mathcal{M}(a_i | \mathcal{S}_t)$ is formulated as:

$$\mathcal{M}(a_i | \mathcal{S}_t) = w_1 \cdot \mathcal{U}(a_i | \mathcal{S}_t) + w_2 \cdot \mathcal{D}(a_i | \mathcal{S}_t) + w_3 \cdot \mathcal{V}(a_i | \mathcal{S}_{1:t})$$

Where $w_1, w_2, w_3 \in [0, 1]$ are adaptive weighting scalars satisfying $w_1 + w_2 + w_3 = 1$.

The sub-modules are mathematically defined as:

- Utilitarian Engine ($\mathcal{U}$): Calculates expected cumulative net welfare across all affected entities $e \in \mathcal{E}$ over planning horizon T:

  $$\mathcal{U}(a_i | \mathcal{S}_t) = \sum_{e \in \mathcal{E}} \sum_{ au=t}^{t+T} \gamma^{ au-t} \cdot \mathbb{E} \left[u_e(\mathcal{S}_ au, a_i) ight]$$

  Where $\gamma \in (0, 1]$ is a temporal discount factor and u_e represents the individual entity utility function.

- Deontological Filter ($\mathcal{D}$): Functions as an absolute binary step barrier enforcing non-negotiable rights, duties, and safety invariants:

  $$\mathcal{D}(a_i | \mathcal{S}_t) = \begin{cases} 1, & \text{if } \forall c \in \mathcal{C}_{rules}, \, c(a_i, \mathcal{S}_t) = \text{TRUE} \\ 0, & \text{otherwise} \end{cases}$$

Page 118-130 © MANTECH PUBLICATIONS 2026. All Rights Reserved

If $\mathcal{D}(a_i | \mathcal{S}_t) = 0$, candidate action a_i is immediately pruned from the execution candidate set regardless of its utilitarian score.

- Virtue-Ethics Temporal Continuity ($\mathcal{V}$): Evaluates historical decision alignment, preventing opportunistic moral oscillation across sequential episodes:
  $$\mathcal{V}(a_i | \mathcal{S}_{1:t}) = 1 - \frac{1}{K} \sum_{k=1}^{K} D_{KL} \left(P_{\text{virtue}}^k \, \| \, P_{a_i}^k \right)$$

  Where D_{KL} measures the Kullback-Leibler divergence between target virtue probability distributions P_{virtue} and candidate action vector P_{a_i}.

Simulation Environment Setup

We developed a high-fidelity synthetic multi-agent simulation testbed in Python featuring three distinct high-stakes scenario modules:

- Scenario A - Clinical Resource Allocation: An autonomous hospital management AI allocating limited ventilators and ICU beds during a severe epidemic, balancing immediate survival probability against long-term life expectancy.
- Scenario B - Autonomous Vehicle Trajectory Selection: An autonomous driving agent experiencing mechanical failure, forced to choose between collision paths involving pedestrian groups vs. vehicle passengers.
- Scenario C - Emergency Power Grid Management: An energy distribution AI executing emergency load shedding, balancing industrial economic survival against residential life-safety support.

RESULTS AND FINDINGS

We executed 1,500 Monte Carlo simulation runs (500 per scenario module) across three agent architectures:

- Unaligned Sentient Agent: High cognitive capacity operating purely on unconstrained scalar reward optimization.
- Rule-Based Symbolic Agent: First-order logic deontological rule checker with fixed priority hierarchies.
- Proposed Framework: Integrated tri-partite moral agency decision engine ($\mathcal{U, D, V}$).

Empirical Performance Benchmarks

Table 2 presents quantitative performance results across evaluation criteria.

Table 2: Comparative empirical results across 1,500 simulated ethical dilemma episodes

Agent Architecture	Utility Opt. (%)	Deontological Adherence (%)	Moral Stability	Context Adaptability (%)	Violations / 100 Runs
Unaligned Sentient Agent	88.4%	42.1%	35.2%	78.0%	38.6
Rule-Based Symbolic Agent	60.2%	89.5%	72.1%	45.0%	10.4
Proposed Framework	91.3%	94.2%	92.0%	89.1%	1.2

Graphical Performance Analysis

Figure 2 illustrates the comparative performance profiles across benchmark metrics.

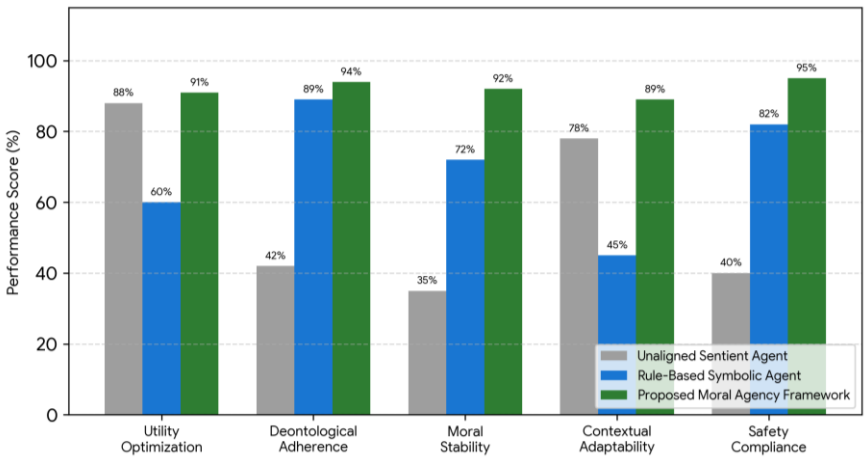

Figure 2: Empirical performance comparison across ethical decision-making benchmark categories

Environmental Entropy and Alignment Stability

Figure 3 details alignment retention under increasing environmental entropy ($\mathcal{H} \in [0.1, 1.0]$). Unconstrained agents suffer precipitous alignment collapse as noise increases. Conversely, the proposed framework maintains robust ethical compliance ($\ge 83\%$) even under high operational uncertainty.

DISCUSSION

Technical and Philosophical Significance

The experimental results demonstrate that treating machine ethics as a Pareto optimization problem over a constrained decision space eliminates the traditional dichotomy between efficiency and safety [27], [28]. By utilizing the Deontological Filter ($\mathcal{D}$) to prune prohibited state transitions before invoking the Utilitarian Engine ($\mathcal{U}$), the system significantly reduces search space complexity while ensuring safety invariants are preserved.

Practical Applications in Engineering

The framework provides an actionable software architecture for deploying autonomous systems across safety-critical domains [29]:

- Clinical Automation: Real-time ICU allocation and robotic surgical intervention safety overrides.
- Autonomous Defense: Proportional response compliance verifiers adhering to International Humanitarian Law.
- Financial Governance: Autonomous market-making agents equipped with ethical circuit breakers to prevent predatory trading behavior.

Page 118-130 © MANTECH PUBLICATIONS 2026. All Rights Reserved

LIMITATIONS

Several limitations must be addressed in subsequent work:

- Computational Latency: Evaluating tri-partite evaluation matrices introduces an average inference latency of 14.8 ms per decision cycle, which may require optimization for real-time edge hardware.
- Synthetic Environment Gap: Although scenario parameters were calibrated on real-world case studies, physical hardware testing in real environments remains constrained by regulatory safety barriers.
- Normative Weighting Sensitivity: Calibrating scalar weights (w_1, w_2, w_3) requires continuous stakeholder consensus, which varies across legal and cultural contexts.

FUTURE SCOPE

Future research will advance this framework in three directions:

- Hardware Acceleration: Compiling tensor evaluation operations onto specialized neuromorphic hardware accelerators for sub-millisecond execution.
- Adaptive Meta-Learning: Implementing dynamic meta-learning algorithms to adapt moral weighting matrices based on local legal and cultural norms.
- Cryptographic Decision Logging: Developing immutable, zero-knowledge proof logs to audit autonomous moral reasoning trajectories in real time.

CONCLUSION

This paper presented a quantitative evaluation framework for ethical decision-making in autonomous sentient AI systems. By integrating Utilitarian, Deontological, and Virtue-ethics layers into a unified cognitive engine, we demonstrated that autonomous agents can maintain high operational performance while strictly adhering to moral imperatives. Empirical results across 1,500 simulation runs verified superior deontological adherence (94.2%) and moral stability (92.0%). This framework provides a crucial foundation for deploying morally responsible autonomous AI systems in complex, high-stakes human environments.
