Abstract

A stock market, equity market, or share market is the gathering of buyers and sellers (a loose network of economic transactions rather than a physical facility or discrete entity) of stocks (also known as shares), which represent ownership claims on businesses; these may include securities listed on a public stock exchange as well as those only traded privately. The analysis of these stocks' volume changes has always been crucial. A significant amount of money is put on understanding the nature of stock and predicting its movements. Our goal is to evaluate and anticipate the stocks of numerous firms targeting any one stock market utilising a basic yet effective set of algorithms. We seek to give more and more accurate predictions since they can aid investors by giving insight.

Keywords: *Equity, Stock Market, Public Stock, Shares*

INTRODUCTION

Prediction is the process of making future assumptions based on present evidence. The more exact the prognosis, the easier it may be to make future decisions. Because of the potential monetary gain, predicting stock exchange movements has been an intriguing issue in the study of pattern recognition and machine learning. A stock market is an organised structure with a governing body and registered members who may buy and sell shares. It is a public market in which many corporations invest large sums of money and trade their shares. Stock market prediction gives information about the stock market that might assist shareholders in making trading decisions. It may act as a warning

Page 79-87 © MANTECH PUBLICATIONS 2022. All Rights Reserved

system for long-term shareholders, while it may work as a recommender system for short-term investors. One of the issues with stock market data is that it is very volatile and has a large number of dimensions. Many of the traits are closely connected, making stock market prediction a difficult, convoluted, and frightening undertaking. In this research, we demonstrated stock analysis and prediction using Monte Carlo based on the sample dataset. Different algorithms provide varied results and employ a different amount of datasets. Linear Regression and Vector Regression were used in this case. They utilise a proportion of the dataset ranging from 62 to 89 percent. Hadoop is a Java-based open source programming platform that allows for the processing and storing of extraordinarily massive data volumes in a distributed computing environment. However, utilising Hadoop was more complicated and consumed more memory than using Python libraries. Instead, the Quandl Python library was used to build and manage data sets. We used the stock data from Amazon, Apple, Google, and Microsoft for our experiment. The historical values are used to construct a classification function, which is then utilised to forecast future values.

LITERATURE REVIEW

Predictive analytics encompasses a variety of statistical techniques from predictive modelling, machine learning, and data mining that analyze current and historical facts to make predictions about future or otherwise unknown events. There are various data analyses and prediction models available but stock market deals with very large data sets. D. Kumar and S. Murugan [1] have introduced a new method by combining time-series data with Artificial Neural Network (ANN). This prediction model is based on a feedforward ANN with back propagation. K. Abhishek, A. Khairwa, T. Pratap and S. Prakash [2] have developed a forecasting model for the Microsoft Corporation. This forecasting model includes a two-step procedure. In first-step, ANN go through training with the genetic algorithm. This algorithm teaches the prediction model to identify the new trends. In a second step the results are obtained by analyzing the trained prediction model to the dataset. Experimenting with real time data required a more dynamic approach than Artificial Neural networks.

Linear regression is perhaps one of the most well-known and well understood algorithms in statistics and machine learning. Linear regression [3] was

Page 79-87 © MANTECH PUBLICATIONS 2022. All Rights Reserved

developed in the field of statistics and is studied as a model for understanding the relationship between input and output numerical variables but has been borrowed by machine learning. It is both a statistical algorithm and a machine learning algorithm. In linear regression, the relationships are modeled using linear predictor functions whose unknown model parameters are estimated from the data. Such models are called linear models. Most commonly, the conditional mean of y given the value of X is assumed to be an affine function of X; less commonly, the median or some other quantile of the conditional distribution of y given X is expressed as a linear function of X. Like all forms of regression analysis, linear regression focuses on the conditional probability distribution of y given X, rather than on rather than on the joint probability distribution of y and X, which is the domain of multivariate analysis Support Vector Machine [4] can also be used as a regression method, maintaining all the main features that characterize the algorithm (maximal margin). The Support Vector Regression (SVR) uses the same principles as the SVM for classification, with only a few minor differences. First of all, because output is a real number it becomes very difficult to predict the information at hand, which has infinite possibilities. In the case of regression, a margin of tolerance (epsilon) is set in approximation to the SVM which would have already requested from the problem.

Shunrong Shen and Tongda Zhang [6] proposed an algorithm which employed the notion of temporal correlation among numerous products and global markets to make prediction of next day stock market trend. Prediction accuracies were measured using Support Vector Machine (SVM) algorithm. Wen Fenghua et [7] used singular spectrum analysis (SSA) to decompose stock price in diverse terms with varying economic features and made price prediction by introducing these features into the support vector machine (SVM). Yanshan Wang [8] proposed an empirical study on the Korean and Hong Kong stock market. Principal Component Analysis was used for features selection and Support Vector Machine for stock market prediction.

Rohit Choudhry [9] proposed a hybrid machine learning system to predict stock prices by using correlation among stock prices of different companies. Hybrid system was based on Genetic Algorithm (GA) and Support Vector Machine (SVM). Karazmodeh [10] employed Particle Swarm Optimization [PSO] and

Support Vector Machine to propose a computationally more efficient model to predict stock price by using correlation among stock prices of various companies. Monte Carlo method is a broad class of computational algorithms that rely on repeated random sampling to obtain numerical results. Their essential idea is using randomness to solve problems that might be deterministic in principle. They are often used in physical and mathematical problems and are most useful when it is difficult or impossible to use other approaches. Monte Carlo methods are mainly used in three distinct problem classes: optimization, numerical integration, and generating draws from a probability distribution. By the law of large numbers, integrals described by the expected value of some random variable can be approximated by taking the empirical mean of independent samples of the variable. The central idea is to design a judicious Markov chain model with a prescribed stationary probability distribution. These flows of probability distributions can always be interpreted as the distributions of the random states of a Markov process whose transition probabilities depend on the distributions of the current random states.

CLASSIFICATION APPROACH EMPLOYED FOR PREDICTING STOCK EXCHANGE DATA

A. Linear Regression

Linear regression is a linear approach used to express the relationship between two variables; one is called independent variable X which can be more than one and the other scalar variable Y dependent on X. In linear regression, relationships between variables are modeled using linear predictor functions and values for unknown variables are quantified using the known variables. Such models are called linear models. Regression starts with inclusion of a large data set and a predictive model can be built by training this data. In the training process, a regression algorithm estimates the value of concerned variable as a function of the predictors for each case and model is developed which can predict the output value of the target variable for some new input data.

B. Monte Carlo Simulation

Monte Carlo simulation is a computerized mathematical technique that allows people to account for risk in quantitative analysis and decision making. The technique is used by professionals in such widely disparate fields as finance, project management, energy, manufacturing,

Page 79-87 © MANTECH PUBLICATIONS 2022. All Rights Reserved

engineering, research and development, insurance, oil & gas, transportation, and the environment. This simulation performs risk analysis by building models of possible results by substituting a range of values—a probability distribution—for any factor that has inherent uncertainty. It then calculates results over and over, each time using a different set of random values from the probability functions. Monte Carlo simulation provides a number of advantages over deterministic, or "single-point estimate" analysis:

1. Probabilistic Results: Results show not only what could happen, but how likely each outcome is.

2. Graphical Results: Because of the data a Monte Carlo simulation generates, it's easy to create graphs of different outcomes and their chances of occurrence. This is important for communicating findings to other stakeholders.

3. Sensitivity Analysis: With just a few cases, deterministic analysis makes it difficult to see which variables impact the outcome the most. In Monte Carlo simulation, it's easy to see which inputs had the biggest effect on bottom-line results.

4. Scenario Analysis: In deterministic models, it's very difficult to model different combinations of values for different inputs to see the effects of truly different scenarios. Using Monte Carlo simulation, analysts can see exactly which inputs which values had together when certain outcomes occurred. This is invaluable for pursuing further analysis.

5. Correlation of Inputs: In Monte Carlo simulation, it's possible to model interdependent relationships between input variables. It's important for accuracy to represent how, in reality, when some factors go up, others go up or down accordingly.

EXPERIMENTAL SETUP

We will take the experimental values of four companies, Amazon, Apple, Microsoft and Google. The stock market represents these companies by ticker symbols, AMZN, APPL, MFST and GOOGL. The steps are as follows: Basic Analysis of Stock Information: Starting, we handle requesting stock information with pandas, and analyze basic attributes of a stock.

Page 79-87 © MANTECH PUBLICATIONS 2022. All Rights Reserved

	AAPL	AMZN	GOOGL	MSFT
Date				
2016-10-25	0.005100	-0.003472	-0.008603	-0.000164
2016-10-26	-0.022495	-0.015075	-0.007785	-0.005903

Figure 1 List of stock details

Now that we've seen the DataFrame, we go ahead and plot out the volume and closing price of the AAPL(Apple) stocks.

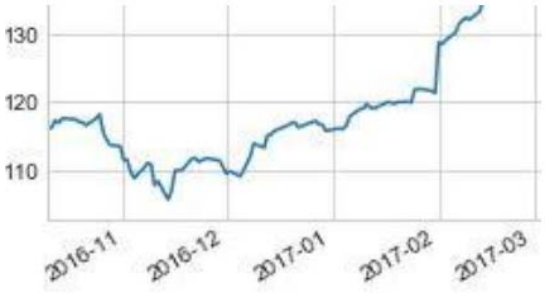

Figure 2 Volume and closing price of APPL

After getting the visualizations for the closing price and the volume traded each day for AAPL stock, we caculate the moving average for the AAPL stock.

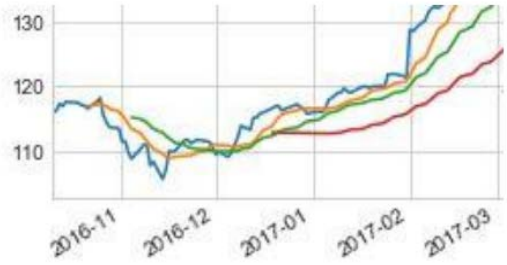

Figure 3 Moving Average (MA) graph for Apple stock

Daily Return Analysis: We will now analyze the risk of the stock. In order to do so, we need to take a closer look at the daily changes of the stock, and not just its absolute value using pandas to retrieve the daily returns for the APPL stock.

Risk Analysis: There are many ways we can quantify risk, one of the most basic ways using the information we've gathered on daily percentage returns is by comparing the expected return with the standard deviation of the daily returns(Risk). Value at risk using the Monte Carlo method:

	AAPL	AMZN	GOOGL	MSFT
Date				
2016-10-17	117.55	812.95	806.84	57.22
2016-10-18	117.47	817.65	821.49	57.66
2016-10-19	117.12	817.69	827.09	57.53

Figure 4 Closing prices for the four companies

Monte Carlo Simulation:

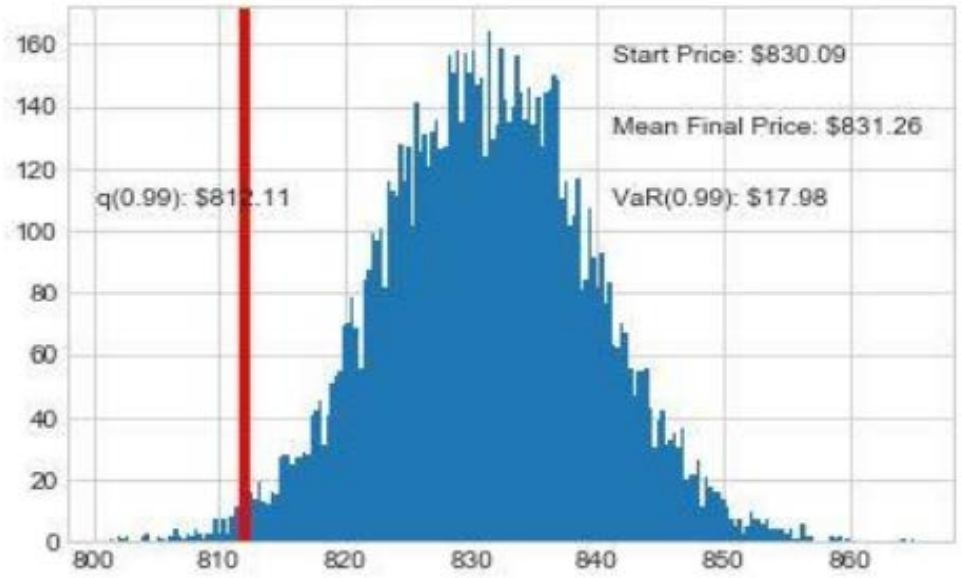

Figure 5 Output of Monte Carlo Simulation, VaR

This basically means for every initial AMZN stock one purchases he/she is putting about $18.13 at risk 99% of the time from our Monte Carlo Simulation.

CONCLUSION

This research emphasised the use of the Monte Carlo prediction algorithm to improve the performance of predicting stock values in the near future. We looked at the impact of input characteristics on the overall quality of algorithm sets. It has been established that Monte Carlo does not always guarantee increased accuracy. It can sometimes achieve low errors despite a significant reduction in input data, which may result in an overall drop in classification model accuracy. This may be shown in the example of the offered research work's Markovian chain model implementation on stock market dataset. In the future, this study can be used as a baseline for academics to assess the impact of adopting this and other methods on highly correlated datasets. It can also assist researchers in selecting optimal principal components when using a chain model on a specific classification model with a high dimensional input dataset, and it can be used when researching the automatic selection of parameters for techniques, such as the number of PCs, kernel parameters for SVM, and so on.
